Difficulty with filing cabinets: Filing cabinets were used for years as a common means of organizing sheets of paper in an office. However, filing cabinets are not good for organizing data in digital form, because the files are hard to find and can get out of order easily. The data they contain may also be difficult to share or backup. In contrast, digital data files are easy to search and share because they can be moved easily and they are easily backed up. There are no cabinets of files, either physical or digital, and data is stored digitally in the cloud. Software programs, including AutoCAD, provide functions for digital data storage and retrieval. Autodesk is an industry leader in the development and design of AutoCAD. Filing Cabinet is a type of physical filing system. It consists of horizontal file drawers and vertical file drawers. A modern version of the filing cabinet is the modern contact file. It consists of a horizontal file drawers and vertical file drawers, much like the traditional filing cabinet. I am trying to build a site which is very similar to a site I'm working on at the moment, however we are using ASP.NET MVC and the current site uses PHP. The problem I'm facing with the current site is that I need to check if the user is logged in. I know that using asp.net MVC this is done with using the FormsAuthentication.RedirectFromLoginPage() method. However on our current site we are using PHP so we can't use this. The reason I'm needing to check if the user is logged in is because I have a form which is saving the user's credentials to a database. On every page of our site we want to display a message if the user is logged in or not. I know that you can write a simple PHP file which will read the server's web.config file and log users in if you're on IIS, however I'm using Apache and we have a htaccess file which directs all requests to PHP files. Therefore I can't use this method because I can't access the web.config file to see if the user is logged in. If anyone has any ideas as to how I can achieve this, I'd be very grateful.

A: You could always have a PHP file which logs in and then look for the cookie in your ASP.NET MVC view. If the PHP file is running on the same server as the ASP.NET MVC view, you can use the cookie. If the PHP file is running on a different server, you can look for the cookie in the ASP.NET MVC view. This is similar to what the FormsAuthentication library does. You could also use this in your PHP file: `$cookie = $_COOKIE['autologin']; if ($cookie) { // User is logged in } else { // Not logged in`
